Figure 10. The Makapansgat pebble with a face from South Africa, which became evidence of human prehistory (John 2007).

recognition in a hand (Bredenk 1995) (Fig. 10). Detecting facial features in non-faces is probably the strongest disposition to pareidolia, prompting pareidolic faces susceptible to strong pareidolia to detect faces even in building facades, natural vegetation, tree bark or burnt loaves, and in several instances on Mars. Magnetoencephalography has found that objects resembling faces evoke a B2 or activation in the occipital fusiform gyrus, which actual faces do slightly earlier (i.e. after 200 ms), whereas other objects appear fail to evoke such an activation altogether (Hadjikhani et al. 2009). This suggests that face perception of face-like objects is not a face cognitive interpretation phenomenon of ambiguous stimuli. Consciousness is almost unresponsive (John 1987), the Makapansgat manuscript is a completely natural product, bearing no artificial modifications (Fednik 1987). Found in an australopithecine-bearing sediment is now placed in the time between 2.8 and 2.9 million years ago (Muller et al. 1979; Muller 1981; Fig. 2).

More recent counterparts of the Lower Palaeolithic that are thought to have attracted hominin pareidolic attention include the Middle-Acheulian The Two-pointed-figure from Morocco (Fednik 2003), the Late Acheulian proto-figure from Beudanticum in hand (Fednik 1986) and the Tefal The A-142 hand artifact from Morocco (Fednik 2003). The two proto-figures have both been modified to replicate their resemblance of human figures, and the Two-Point

figures has been created with hominids. The Tefal example clearly resembles a human figure and has been carved for a great distance, before having been deposited among Late Acheulian artefacts within a ritualised context by choice.

Therefore the belief of the collection of thousands of 'figure stones', that such recognition of iconic properties in natural products was possible for people of the Lower Palaeolithic, is indeed justified. However, the great majority of these collected stones were not found in decontaminated, unoccupied sites, therefore no means exists to measure that they attracted hominin attention. The main justification for these 'figure stones' being artefacts is that they triggered a pareidolic reaction in their makers. But a small percentage of all these objects is naturally better pieces of this should be expected to do so, in people who have high susceptibility to pareidolia. Even if the finds come from an occupation deposit, at least one of two further requirements must be met. They must either present forensic evidence of human work there, or they have to be of a material that cannot occur at the site by purely natural transport. Thousands of naturalistic material had to meet these requirements. Of all the people involved in their study, only Richard Wrangham (<http://www.psnat.com/>) and Alan Day have contributed to naturalistic scientific reasoning and presentation into the issue.

Over the past 20 years the author has received many dozens of submissions concerning such believed to possess iconic properties, in the form of thousands of photographs and sometimes actual specimens. One Australian pebble with a lifting of all facial outline and posture that were entirely unmodified and included no stone in which the author could recognize whatever they were thought to resemble. Another reported that the hand image within small pebbles when she broke them open, and she proposed that these representations had been placed deliberately by Aboriginals. Unable to appreciate what she meant, we tried her to send two or three specimens, allowing a certain excellent study chance of hand and posture. The author saw no images on their fracture surfaces. On another occasion he examined Gadsby's figure, a pebble with an Australian hand, in Central Australia (H11 and H11 1978, 89). The event was very hard to compare like that, in addition to the direct several excellent photographs, there is also very intricate discussion on the accompanying rock surface. Unable to see what she meant it took some time to realize that she perceived the general, calcification-like features of pebble patterns on the rock pavement as having been created by humans. Our explanation of the phenomenon as natural mineral accretions and their modifications was met with hostility.

There is an inherent precedent for these

The song itself is absolutely brilliant, everything seems to be arranged and written in such a way that you always long for more while listening to the specific parts of the album at the end of each track and the album itself makes you feel Thoroughly met.

resemblance to a hand (Bridgman, 1990) (Fig. 10). Detecting facial features in non-fossils is probably the strongest disposition to pareidolia, perceiving pareidolia (those susceptible to strong pareidolia) in infant faces even in building facades, natural vegetation, tree bark or beach boats, and in several instances on Mars. Magnetoencephalography has found that objects resembling faces evoke a 10% activation in the occipital fusiform gyrus, which actual faces do slightly earlier (i.e. after 200 ms), whereas other concrete objects fail to evoke such an activation altogether (Haxby et al. 2005). This suggests that face perception of face-like objects is not a late cognitive interpretation phenomenon of ambiguous stimuli. Current face selectivity suggests (Fahle, 1997) the Makapansgat fragment is a completely natural product, bearing no artificial modification (Feldman, 1997). Found in an australopithecine-bearing sediment it was placed in the cave between 2.8 and 2.9 million years ago (Muller et al. 1979; Mulholland, 1990; Fig. 2).

More recent counterparts of the Lower Palaeolithic that are thought to have attracted hominid pareidolia attention include the Middle Acheulian Ten-Ten proto-figurine from Morocco (Bridgman, 2001), the Late Acheulian proto-figurine from Benoit's Cave in Israel (Goren-Livnat, 1996) and the Tefen 104-2 fossil watch's case from Morocco (Feldman, 2005). The two proto-figurines have both been modified to emphasize their resemblance to human figures, and the Ten-Ten

specimens had been created with hominids. The Tefen 104-2 sample clearly resembles a human profile and has been covered for a great distance, before having been deposited among Late Acheulian artefacts within a ritualised context of choice.

Therefore the belief of the collection of thousands of 'Spang' stones; that such recognition of iconic properties in natural products was possible for people of the Lower Palaeolithic, is indeed justified. However, the great majority of these collected stones were not found in decontextualised recognition sites, therefore no reason exists to assume that they attracted hominid attention. The main justification for these 'figures' comes from artefacts in that they triggered a pareidolia reaction in their finders. But a small percentage of all these objects or naturally broken pieces of flint should be expected to do so, in people who have high susceptibility to pareidolia. Even if the flint came from an occupation deposit, at least one of two further requirements must be met, they must either present forensic evidence of human work there, or they have to be of a material that cannot occur at the site by purely natural processes. Thousands of stones of the mentioned flint in most cases requirements. If all the people involved in their study, only Richard White (http://www.paleoart.com/) and Alex Tera have volunteered to interpret scientific reasoning and presentation into the text.

Over the past 20 years the author has received every degree of rudeness concerning such behaviour to protect human properties, to the loss of thousands of photographs and specimens at actual expeditions. One Australian pareidolia artist (Fig. 1) of all natural objects and fossils that were initially considered and included in those to which the author could recognize whatever they were thought to resemble. Another reported that the hand image within fossil patterns when she looks them, eyes, and she proposed that these representations had been placed deliberately by Neanderthals. Unable to appreciate what she meant, we looked but to need two or three specimens, adding a matrix containing many dozens of hand and fossils. The author was in charge of their fracture surfaces. On another occasion he presented 'Cretaceous' fossils, a photograph of an 'Australopithecine' in Canada's fossil record (Hil and Hill 1976, 80). The object itself very hard to recognize like that, in addition to the strict natural earliest petroglyphs, there is also very intricate decoration on the underlying rock surface. Unable to see what she meant it took some time to realize that she perceived the general, calcification-like face of a paleo-pictorial on the rock surface as having been created by humans. Our explanation of the phenomenon as natural mineral reactions and their modification was not well received.

There is an inherent precedent for those
